**Abstract.** We compared the isolated populations of *Lyciasalamandra atifi*, (Başoğlu, 1967) a salamander endemic to the historic Lycia region of Turkey, that is found across a range from Antalya/Selge (Altinkaya) to Antalya/Gazipaşa. Along this distance, we determined eight isolated populations (Selge, Fersin, Dikmen, Güzelbağ, Türbelinaz, Gündoğmuş, Cebireis, Gazipaşa) in 2013 and used morphology and serology to compare them. The collected specimens were registered under the ZMADYU (Zoology Museum of Adiyaman University), and a total of 237 (59 ♂♂, 96 ♀♀, 82 juv.) specimens were studied. As a result of our research, three new subspecies are described: *Lyciasalamandra atifi godmanni* n. ssp. from Selge, *Lyciasalamandra atifi veithi* n. ssp. from Dikmen and *Lyciasalamandra atifi kunti* n. ssp. from Güzelbağ. Except Cebireis (*L. a. bayrami*) and Gazipaşa (*L. a. oezi*) populations, the other isolated populations were incorporated in the nominat subspecies due to morphological and serological similarities.

**KEY WORDS:** *Lyciasalamandra atifi* *veithi* n. ssp., *Lyciasalamandra atifi* *godmanni* n. ssp., *Lyciasalamandra atifi* *kunti* n. ssp., distribution, Antalya, serology.

## INTRODUCTION

The Lycian salamander was first identified by Steindachner (1891) as *Molge luschani* from the village of Dodurga in Turkey's Muğla province. It was transferred to the genus *Mertensiella* by Wolterstorff (1925) and eight taxa were subsequently identified as subspecies of *Mertensiella luschani*. The specimens from Dodurga was also accepted as the nominate subspecies of *Mertensiella luschani*. (Veith et al. 2001, Göçmen et al. 2011).

*Lyciasalamandra atifi* was found in February 1966 for the first time during a zoological excursion on the road between Alanya-Türbelinaz by Atif ŞENGÜN (one male and three juveniles). These specimens were different from the other *Mertensiella luschani* subspecies with regard to size and colouration. As a result, these specimens were described as *Mertensiella luschani atifi* and dedicated to Atif ŞENGÜN, who found them for the first time (Başoğlu 1967). In the light of recent molecular studies, the taxonomical status of these viviparous tailed amphibians was revised and assigned to the genus *Lyciasalamandra* by Veith and Steinfartz (2004) after detailed mitochondrial and allozyme data studies.

Until recently, it was known that there were 9 allopatric species and 16 taxa among Lycian salamanders between Muğla/Marmaris and Antalya/Gazipaşa along a distance of 420 km in southwestern Turkey. These were: [*Lyciasalamandra luschani luschani* (Steindachner, 1891); *L. atifi atifi* (Başoğlu 1967); *L. fazilae* (Başoğlu & Atatürk 1974); *L. luschani finikensis* (Başoğlu & Atatürk 1975); *L. antalyana antalyana* (Başoğlu & Baran 1976); *L. luschani basoglu* (Baran & Atatürk 1980); *L. billae billae* (Franzen & Klewen 1987); *L. flavimembris flavimembris* (Mutz & Steinfartz 1995); *L. irfani* Göçmen et al. 2011; *L. arikani* Göçmen & Akman 2012; *L. yehudahi* Göçmen & Akman 2012; *L. antalyana gocmeni* Akman & Godmann 2014; *L. atifi bayrami* Yıldız & Akman 2015; *L. flavimembris ilgazi* Üzüm et al. 2015; *L. billae eikeae* Godmann et al. 2016; *L. atifi oezi* Tok et al. 2016]. According to recently published paper by Veith et al. (2016), based on levels of molecular differentiation *L. arikani*, *L. irfani* and *L. yehudahi* were considered as subspecies of *L. billae*. Currently, 6 allopatric species and 16 taxa exist in Turkey.

Except for *L. luschani basoglu* (Baran & Atatür 1980), which exists in Megisti (Kastellorizo) island and *L. helverseni* (Pieper 1963) that lives on some Greek islands (Saria, Kasos & Karpathos), other taxa are endemic to Turkey (Eleftherakos et al. 2007). *Lyciasalamandra atifi* has the largest distribution range among the species of *Lyciasalamandra* (Akman et al. 2011; Göçmen et al. 2013). It was known from Selge to Alanya along a range of 110 km. Recent studies, Akman et al. (2011) and Göçmen et al. (2013) report that the species' range extends until Antalya/Gazipaşa, and up to 1400 m above sea level. Consequently, the range of *L. atifi* has been extended to 185 km.

## MATERIALS AND METHODS

To clarify the differences between *Lyciasalamandra atifi* populations, we conducted excursions in February and March in 2013. We stated eight isolated populations (Fersin, Selge, Dikmen, Güzelbağ, Türbelinaz, Gündoğmuş, Cebireis Mountain, Gazipaşa) and used morphology, serology, statistics techniques to compare them. These techniques for each population were methodically described.

The collected specimens were registered under the ZMADYU (Zoology Museum of Adiyaman University) and a total of 237 (59♂, 96♀, 82 juv.) specimens were studied. These specimens were subjected to morphological and serological studies. To capture the ecological differences between populations and biotopes, we used Canon 1100D and Sony DCS-W510 digital cameras. Sea levels and coordinates of populations measured by using a Macellan XL GPS device.

Some specimens were studied for serology experiments by taking blood samples and the others were etherized, then injected with 96% ethanol solution and stored in glass jars containing 96% ethanol to facilitate future DNA analyses. All collected specimens were deposited in Zoology Museum of Adiyaman University (ZMADYU).

To facilitate population comparisons regarding blood-serum proteins, polyacrylamide gel electrophoresis (PAGE) and densitometric analyses were utilized. Blood samples were obtained in the laboratory within three days of collection after anaesthetizing with ether, by ventral abdominal vein puncture with heparinized hematocrit capillary tubes. The separation of blood-serum proteins followed the polyacrylamide "disc" electrophoresis method of Davis (1964), slightly modified by Arikhan (1983).

Metric characters were measured with a Mitutoyo digital caliper of 0.02 mm sensitivity, except total body length, rostrum-anus length and tail length, which

were measured by a millimetric ruler. Summarized statistics were conducted with SPSS 15.0 for Windows. Furthermore, to control the test results of raw metric characters, they were tested again with a Student's t-test that took indexed values of PERCRA (percents of Rostrum-Anus Length; [each metric character / RA] × 100), which improved the analysis. The evaluation of all statistical analyses was based on the statistical significance level of " $p \leq 0.05$ " (Werner 1971).

We applied ANOVA and discriminant analyses for each population and Student's t-test to evaluate potential sexual dimorphism in each population. For mensural (metric) character comparison we also used subadults (higher value of 65 mm by Rostrum-Anus Length), to avoid effects of allometry. Mensural (metric) characters: Total Body Length –the length of the whole body including the tail (TBL), Rostrum-Anus Length –length from the snout to the posterior end of the cloacal opening (RA), Length of Trunk –length from gular fold to the anterior edge of cloacal opening (LT), Tail Length (TL), Nostril-Eye Distance (NED), Distance Between Nostrils (DBN), Eye Diameter (ED), Head Length –distance from the snout to the gular fold (HL), Head Width (HW), Parotoid Length (PL), Parotoid Width (PW), Fore Limb Length (FLL), Hind Limb Length (HLL), Distance between Fore-and-Hind Limbs (DFHL), Height of dorsal protuberance on base of the tail (HPBT) –only in males.

Ethical permission (Ege University Animal Experiments Ethics Committee, 2013#028) as well as special permission (2013#220762) for the field studies from the Republic of Turkey, Ministry of Forestry and Water Affairs were received.

## RESULTS

### Selge Population

A total of 32 specimens (11 males, 10 females, 11 juveniles) were studied from Selge-Köprülü Canyon. Specimens were found during daytime, at a temperature of 19.7 °C, on a steep slope beneath the limestone ridges, and at a time of humid and cloudy weather at 482m a.s.l. Habitat photos of Selge population are given in Figure 1.

#### Colouration and Pattern

Males: The background colour of the adult males of the Selge population is

reddish dark brown, eye lids and the posterior of parotoid glands have yellow spots. On the back there are white spots along the paravertebral sides until the tail base. Background colouration continues in the tail. A white stripe begins under the eye line and lasts until the fore limbs uninterruptedly. This pattern exists in all males.

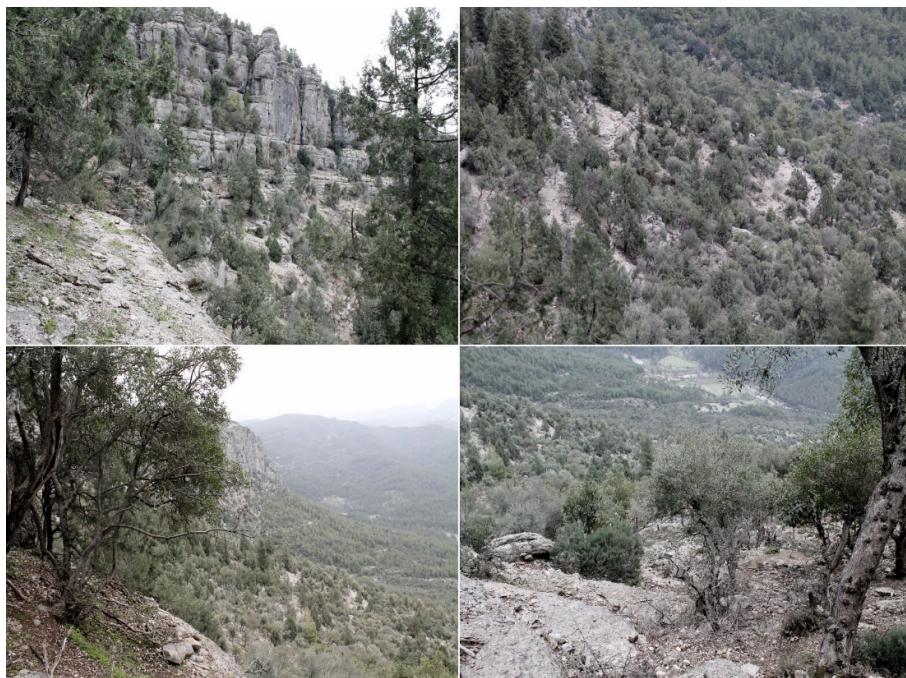

Figure 1. Habitat of the Selge population from different views.

**Females:** Background colouration is similar to males. There are yellow spots on the posterior of the eye lids and parotoid glands. Scattered white spots start from the top of the head and continuous until the tail tip. A white stripe begins under the eye line on both right and left sides, lasts until the fore limbs, as in the males. All females have that uninterrupted white stripe pattern.

**Juveniles:** Posterior of parotoids have yellow colouration. The entire body has white spots, which are randomly scattered on the back and per-

sist until the fingertips and the body is dominated by a reddish dark brown dorsal ground colour. Juveniles have a reddish fleshy tone in the ventral aspect, scattered white spots are also visible. Photos of specimens from Selge population are in Figure 2.

Figure 2. Specimens from Selge. a) Adult male b) Adult female  
c) Juvenile d) Dorsal view of a juvenile

#### Serological Evaluation

Blood serum proteins of a male and female individuals from Selge population, were evaluated by polyacrylamide disc electrophoresis method. Both male and female blood samples were divided into 12 fractions. 10 of them were found in the globulin, 1 albumin and 1 pre-albumin. Figure 3 shows the electrophoretic separation of blood serum proteins.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and

morphological characters. Summarized statistics and P values from the raw data, ratios and PERCRA index values are given in Table 1. The abbreviations are provided in the Materials and Methods section. According to the Student's t test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (Eye Diameter, Head Length, Head Width and Parotoid Length).

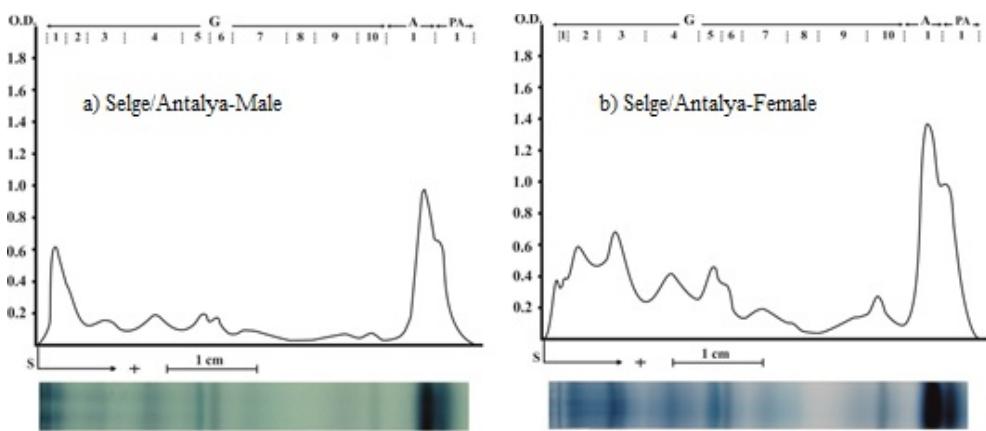

Figure 3. Electrophoretic separation of blood serum protein electropherograms and densitometric curves of the Selge population. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region)

### Fersin Population

31 specimens (9 males, 16 females, 6 juveniles) were studied from Fersin/Güçlüköy. We found the specimens under limestone slabs in daytime. The weather was humid and cloudy, the terrain was smooth, with high vegetation. Some specimens were found sheltering inside historical walls. The photos of the habitat of Fersin are in Figure 4.

#### Colouration and Pattern

Males: The background colour is dark brown and continues to the finger-

Table 1. Body measurements, PERCRA index values and Student's t-test analyses results of the Selge population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean;  $p \leq 0.05$ . The other abbreviations of characters are given in Materials and Methods.

tips. There are white spots on the head and on the back, along the paravertebral lines until the base of the tail. There are discontinuous white stripes that start under the eye level and continue between the fore and hind limbs.

Figure 4. Habitat of the Fersin population from Fersin/Güçlüköy.

**Females:** Posterior of the eyelids and parotoid glands have scattered white spots on the head. Limbs, discontinuous white stripes on right and left sides and the ground colouration are the same colouring scheme with males.

**Juveniles:** Posterior of the parotoids on juvenile specimens have yellow spots in the back part of the head and there are many white spots. Body and tail colouration is the same as in adult specimens. Photos of specimens from the Fersin population are in Figure 5.

#### Serological Evaluations

Blood serum proteins of a male and female from Fersin were evaluated by polyacrylamide disc electrophoresis method. Blood serum sample of the male specimen divided into 12 fractions. 10 of them were found in the globulin zone, others are albumin and pre-albumin proteins. Female samples divided into 11 fractions. There are 9 globulin, 1 albumin and 1 pre-albumin. Figure 6 shows the electrophoretic separation of blood serum proteins of Fersin population.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes

Figure 5. Specimens from Fersin. a) Adult male b) Adult female  
c) Juvenile d) Ventral view of a juvenile.

and morphological characters. Summarized statistics and  $p$  values from the raw data, ratios and PERCRA index values are given in Table 2. According to the Student's t test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (Head Length and Head Width).

### Dikmen Population

25 specimens (6 males, 11 females, 8 juvenile) were found in Dikmen/Akseki region. In this place, specimens were found in walls left over from ancient settlements. It was hard to reach the specimens inside the walls, so fieldwork continued into the night to acquire enough specimens for statistics. The weather was humid and cloudy, temperature of 17°C. Habitat photos of Dikmen population are given in Figure 7.

Figure 7. Habitat photos from Dikmen and views of the old walls that sheltered the specimens.

### Colouration and Pattern

**Males:** Background colour is dark brown and there are white spots on the eyelids, anterior of the parotoids and in the back in a scattered pattern. Posterior of the parotoids have yellowish spots. Dorsal part of the tail is light brown and white spots at the limbs continue to the fingertips. No white striping on lateral parts.

**Females:** Yellowish spots are visible posterior of the parotoids. In the dorsal of the body, there are white spots on a dark brown background colour. The dorsal colouration of the tail is light brown. No white striping on lateral parts.

**Juveniles:** Yellow spots on the posterior of the parotoids are visible in juveniles. In the dorsal, there are scattered white spots on the head and back on a dark brown background colouration. Other colour pattern features are the same as males. Photos of specimens from the Dikmen population are in Figure 8.

Figure 8. Specimens from Dikmen. a) Adult male b) Adult female c) Juvenile d)  
Dorsal view of adult female, adult male and juvenile.

#### Serological Evaluations

Blood serum proteins of a male and female from Dikmen population were evaluated by polyacrylamide disc electrophoresis method. Both male and female blood serum samples were divided into 11 fractions. Nine of them

were found in the globulin, 1 albumin and 1 pre-albumin (Figure 9).

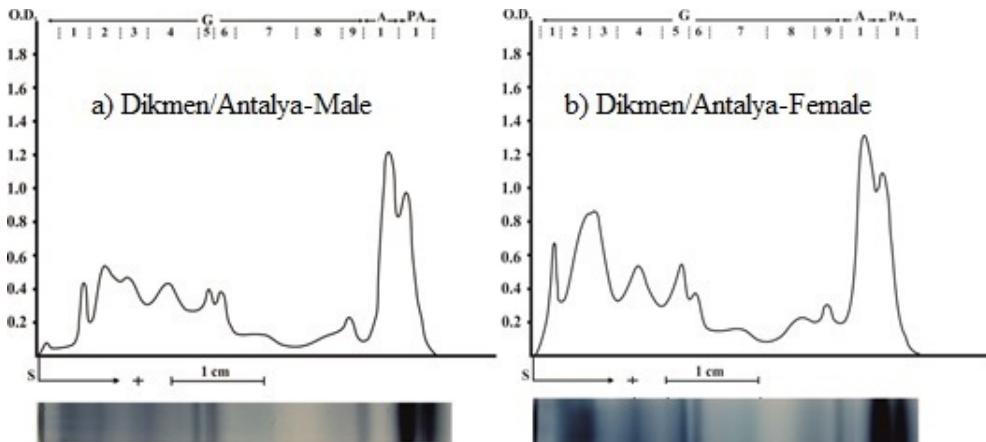

Figure 9. Electrophoretic separation of blood serum protein electropherograms and densitometric curves of the Dikmen population. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region).

#### Body measurements and rate

The Student's t-test indicated significant differences between the sexes and morphological characters. Summarized statistics and  $p$  values from the raw data, ratios and PERCRA index values are given in Table 3. According to the Student's t-test, we couldn't determine statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values.

#### **Gündoğunş (Bayırköy) Population**

The Gündoğunş population is 9 km away from Güzelbağ and near the Bayırköy/Takanlar neighborhood. A total of 20 specimens (5 males, 8 females, 7 juveniles) were found in the area. The weather was cloudy, humid, temperature of 17.5°C and the elevation was 710m a.s.l. Habitat photos of the Gündoğunş population are in Figure 10.

Table 3. Body measurements, PERCRA index values and student T-test analyses results of Dikmen population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean;  $p \leq 0.05$ . The other abbreviations of characters are given in Materials and Methods.

Figure 10. Habitat photos of the Gündoğmuş population.

#### Colouration and Pattern

**Males:** Head and background colour of the males is dark brown and white spots on the parotoids are visible. Dorsally, white spots continue along the paravertebral lines until the tail base. On the sides, there are intermittent white stripes which start under the eye level and continue between the fore and hind limbs. The background colour continues to the fingertips.

**Females:** Head and background colour in females contain scattered white spots on a dark brown colouration. On the sides, intermittent white stripes start under the eye level and ongoing continue between the fore and hind limbs. The background colour continues to the fingertips.

**Juveniles:** Intense and scattered white spots present at the eyelids around the parotoid glands and yellow spots are visible on the parotoids. White spots on the body continue intermittently to the fingertips on the dark brown background colour. Photos of specimens from Gündoğmuş population are given in Figure 11.

#### Serological Evaluations

Blood serum proteins of a male and female from Gündoğmuş, were evaluated by the polyacrylamide disc electrophoresis method. Blood serum samples of the male were divided into 12 protein fractions. 10 of them were found in globulin and the others are albumin and pre-albumin, female's blood serum samples were divided into 13 fractions. There are 11 globulin and 1 albumin and 1 pre-albumin proteins. Figure 12 shows the electropho-

Figure 11. Specimens from Gündoğmuş. a) Adult male b) Adult female  
c-d) Juveniles.

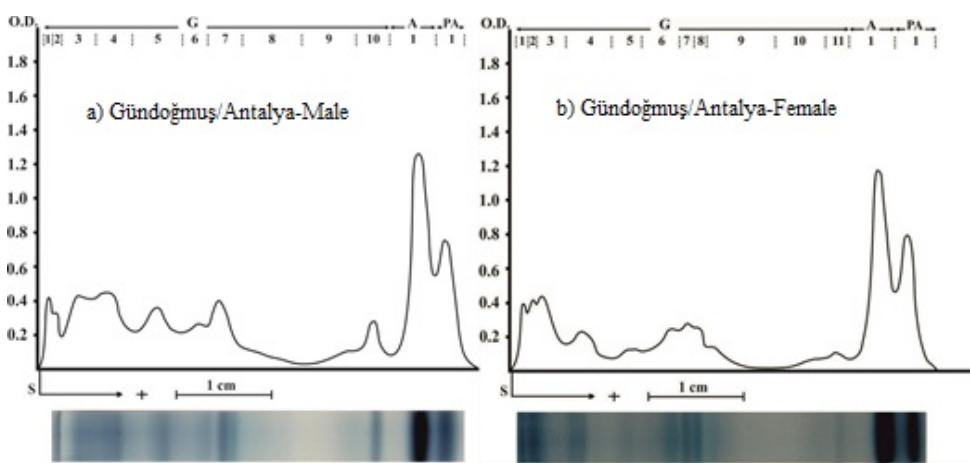

Figure 12. Electrophoretic separation of the Gündoğmuş population, blood serum protein electropherograms and densitometric curves. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region).

Table 4. Body measurements, PERCRA index values and Student's t-test results of the Gündoğmuş population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean; P≤0.05. Other abbreviations of characters are given in Materials and Methods.

retic separation of blood serum proteins of the Gündoğmuş population.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and morphological characters. Summarized statistics and  $p$  values from the raw data, ratios and PERCRA index values are given in Table 4. According to the Student's t-test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (Distance between nostrils).

#### **Güzelbağ Population**

A total of 28 specimens (6 males, 12 females, 10 juveniles) were found in Güzelbağ. The weather was rainy, temperature of 18°C and the elevation was 829 m a.s.l. The specimens collected from under the white-striped limestone rocks. The field was smooth open. Habitat photos of the Güzelbağ population are in Figure 13.

Figure 13. Habitat photos of the Güzelbağ population.  
Habitat destruction is visible on the right-hand photo.

#### Colouration and Pattern

**Males:** Background colour is dark brown and there are markedly large white spots on the head and dorsum, which continue until the fingertips. Yellow spots are visible at posterior of the parotoids. In the sides, there are frag-

mented and discontinuous white stripes which start under the eye level and go on between the fore and hind limbs.

**Females:** There are white spots at the above the head and yellow ones posterior of the parotoids. Background colour is dark brown but, unlike males, white spots are smaller and less in number. On the sides, there are intermittent white stripes which start under the eye level and continue between the fore and hind limbs.

**Juveniles:** There are yellow spots at the posterior of the eyelids and the parotoids. Numerous scattered white spots on dark brown background colour continue to the fingertips. Photos of specimens from the Güzelbağ population are in Figure 14.

Figure 14. Specimens from Güzelbağ a) Adult male b) Adult female  
c) Juvenile d) View of an adult female, adult male and a juvenile.

#### Serological Evaluations

Blood serum proteins of a male and female from the Güzelbağ population,

were evaluated by the polyacrylamide disc electrophoresis method. Both male and female blood samples were divided into 11 fractions, 9 of them were found in the globulin zone, 1 albumin and 1 pre-albumin proteins. Figure 15 shows the electrophoretic separation of blood serum proteins.

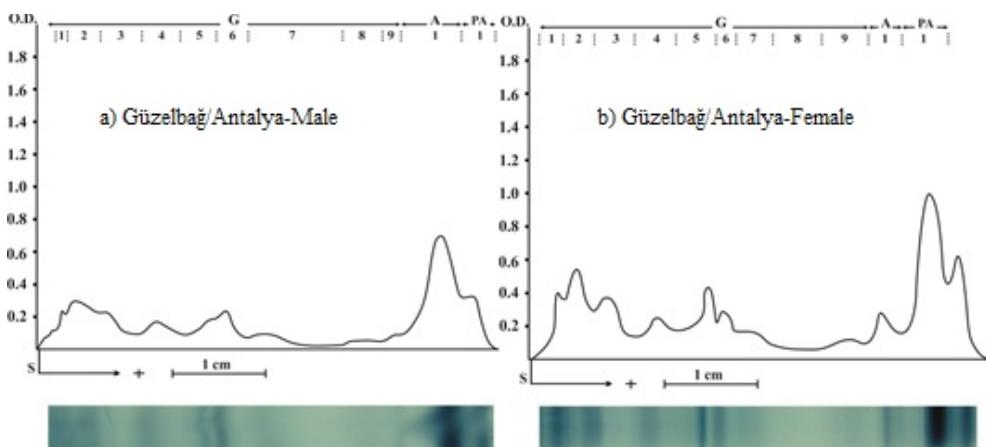

Figure 15. Electrophoretic separation of the blood serum protein electropherograms and densitometric curves of the Güzelbağ population. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and morphological characters. Summarized statistics and  $p$  values from the raw data, ratios and PERCRA index values are given in Table 5. According to the Student's t-test, we could not determine statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values.

#### **Türbelinaz Population**

30 specimens (7 males, 16 females, 7 juveniles) were found in Türbelinaz. They were found beneath the limestones when the weather was sunny and

Table 5. Body measurements, PERCRA index values and Student's t-test results of Güzelbağ population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean;  $p \leq 0.05$ . The other abbreviations of characters are given in Materials and Methods.

clear. Habitat photos of Türbelinaz population are given in Figure 16.

Figure 16. Habitat photos of Türbelinaz population from Türbelinaz/Alanya.

#### Colouration and Pattern

**Males:** Yellow spots are visible at the eyelids and posterior of the parotoids. There are white spots in rows extending to the base of the tail on the dorsum. A continues white stripe is available between the fore and hind limbs.

**Females:** There are yellow spots on the head and posterior of the parotoids. Scattered white spots are commonly seen on the dorsal surface, on a dark brown background colour. Colour of limbs and the lateral stripes are as in males.

**Juveniles:** Yellow spots on the parotoids and scattered white spots on the eyelids are seen. Other details the same as those adult populations on a dark brown background colour. Dorsal section of the tail is covered with the yellow spots and continues to fingertips. Photos of specimens from the Türbelinaz population are in Figure 17.

#### Serological Evaluations

Blood serum proteins of a male and female from Türbelinaz, were evaluated by polyacrylamide disc electrophoresis method. Blood serum sample of male was divided into 12 fractions. 10 of them were found in the globulin zone, others are albumin and pre-albumin. Female's blood serum sample was divided into 11 protein fractions. There are 9 globulin and 1 albumin

Figure 17. Specimens from Türbelinaz. a) Adult male b) Adult female  
c) Juvenile d) Dorsal view of adult female, adult male and juvenile.

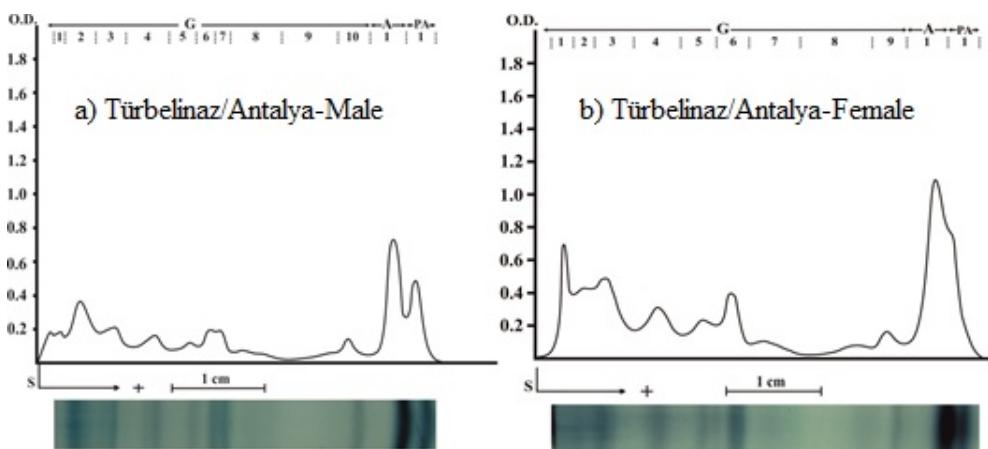

Figure 18. Electrophoretic separation of blood serum protein electropherograms and densitometric curves of the Türbelinaz population (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region).

Table 6. Body measurements, PERCRA index values and Student's t-test results of Türbelinaz population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean;  $p \leq 0.05$ . The other abbreviations of characters are given in Materials and Methods.

and 1 pre-albumin proteins. Figure 18 shows the electrophoretic separation of blood serum proteins of Türbelinaz population.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and morphological characters. Summarized statistics and  $p$  values from the raw data, ratios and PERCRA index values are given in Table 6. The abbreviations are provided in the Materials and Methods section. According to the Student's t-test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (TBL, LT, TL, HL, FLL, DFHL and TL/TBL).

#### **Cebireis Population**

On Cebireis Mountain, near the Yalçı village, Kaplanhanı plateau, Dim river and Kuşyuvası region, we found 40 specimens (6 males, 11 females, 23 juveniles). Cebireis Mountain has the largest distribution of *Lyciasalamandra atifi* among other populations. This population was described as *Lyciasalamandra atifi bayrami* by Yıldız and Akman in 2015. We also applied serological comparison and statistics to facilitate the differences among the populations.

#### Colouration and Pattern

**Males:** There are yellow spots on the posterior of the parotoids and continuous white spots are visible on paravertebral lines until the base of the tail. An uninterrupted white stripe starts from the eyes level and continues between the fore and hind limbs at lateral sides. The background colour is dark grey but the dorsal aspect of the tail is dark brown.

**Females:** The dorsal sides of the head and the back shows grayish dark brown colouration and there are no white spots on the dorsal surface. An uninterrupted white stripe at the lateral sides, and the tail colouration is similar to male specimens. Yellow spots are visible posterior of the parotoids.

**Juveniles:** Posterior of the eyelids and parotoids have yellow spots and there is an intense speckling of white spots on the entire body. The back-

ground colour is dark brown and yellow spots can be seen on the dorsal surface and the tail. Photos of specimens from Cebireis population are given in Figure 19.

Figure 19. Specimens from Cebireis. a) Adult male b) Adult female  
c) Juvenile d) Dorsal view of adult female, juvenile and adult male.

#### Serological Evaluations

Blood serum proteins of a male and female from Cebireis population were evaluated by the polyacrylamide disc electrophoresis by Yıldız and Akman, 2015. We put the same graphic to compare with the others. Both male and female blood samples were divided into 12 fractions. 10 of them were found in the globulin, 1 albumin and 1 pre-albumin proteins. Figure 20 shows the electrophoretic separation of blood serum proteins.

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and

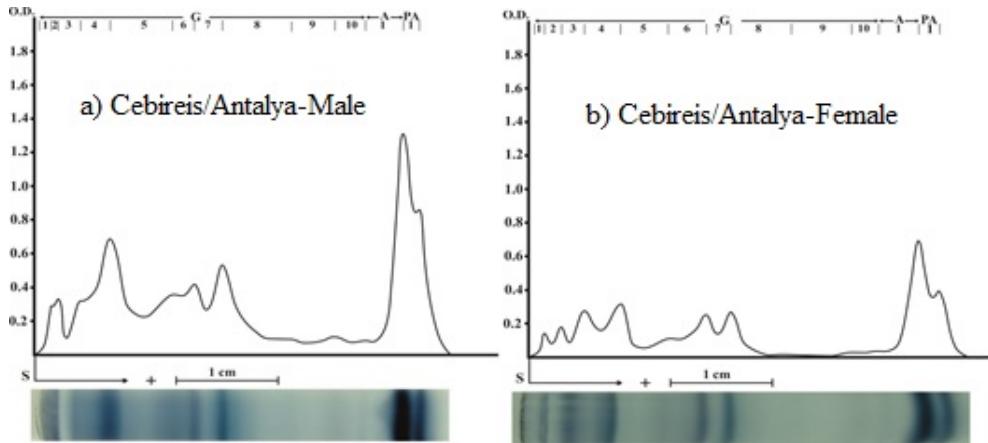

Figure 20. Electrophoretic separation of blood serum protein electropherograms and densitometric curves of the Cebireis population. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Pre-albumin. A: Albumin region) (From Yıldız and Akman, 2015).

morphological characters. Summarized statistics and P values from the raw data, ratios and PERCRA index values are given in Table 7. The abbreviations are provided in the Materials and Methods section. According to the Student's t-test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (RA, TBL, LT, DBN, HW and HLL).

### Gazipaşa Population

31 (9 males, 12 females and 10 juveniles) specimens were found during fieldwork in Gazipaşa. *Arbutus arachnoides* (the Greek strawberry tree) is abundant at the area, and specimens shelter under limestone slabs at the moisture-holding roots of the trees. Three localities were found by Göçmen et al. 2013 (Karaçukur, Çığlık, Gürçam) and three new localities were found during our excursion in April 2015. The localities are Daşılıbük mevkii (Çakmak - Çörüş village road), Küçüklü village and İllica village; during search the weather was cloudy and temperature was 18°C. Habitat photos

of the Gazipaşa population from Daşılıbük mevkii and Gürçam are in Figure 21, Küçüklü and İllica village are in Figure 22. This population was described as *Lyciasalamandra atifi oezi* by Tok et al. (2016).

Figure 21. Habitat photos of Daşılıbük in left-hand and Gürçam where *Arbutus ardachne* (the Greek strawberry tree) plants are visible, alongside moisture-retaining limestone slabs in right-hand photo.

Figure 22. Habitat photos from Küçüklü and İllica village respectively.

#### Colouration and Pattern

**Males:** The background colour is dark brown and there are no white spots on the dorsal surface of the head, but white spots exist along the paravertebral lines until the base of the tail. An uninterrupted white stripe starts from the eye level and continues between the fore and hind limbs at lateral sides.

**Females:** The background colouration is completely dark brown and

there are no white spots on the dorsal surface of the body. As in the adult males, the white stripe, starts at the eye level continues between the fore and hind limbs.

Juveniles: The dorsal aspect of the head and body have a large amount of white spots, but there is no yellowish colouration on the parotoids. The white stripes between the fore and hind limbs exist as in the males and females, and the white spot on the dorsal surface of the body continues until the tail tip. Photos of specimens from the Gazipaşa population are in Figure 23.

Figure 23. Specimens from Gazipaşa. a) Adult male b) Adult female  
c) Juvenile d) Dorsal head view of a juvenile.

#### Serological Evaluations

Blood serum proteins of a male and female from Gazipaşa population were evaluated by the polyacrylamide disc electrophoresis method. Both male and female blood samples were divided into 13 fractions. 11 of them were found

in the globulin, 1 albumin and 1 pre-albumin proteins. Figure 24 shows the electrophoretic separation of blood serum proteins.

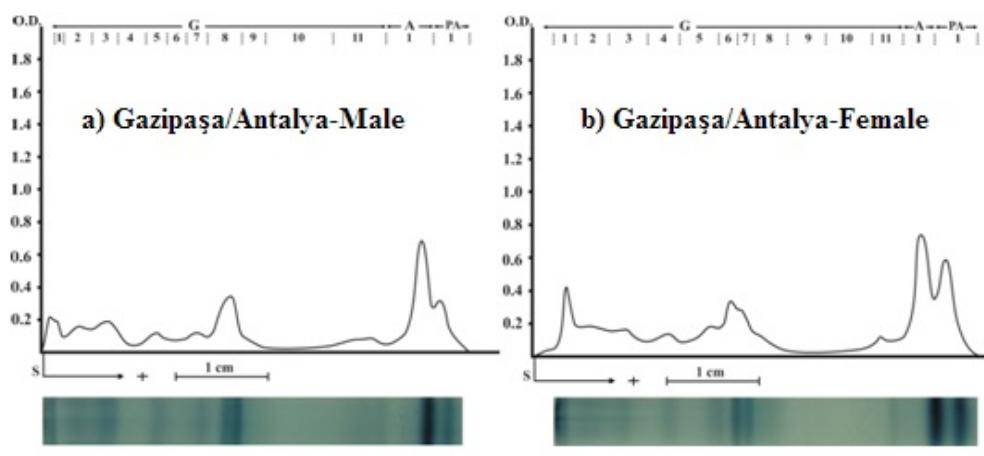

Figure 24. Electrophoretic separation of blood serum protein electropherograms and densitometric curves of the Gazipaşa population. (OD: optical density. S: Border between the stacking gel and separating gel. G: Globulin region. PE: Prealbumin. A: Albumin region).

#### Body measurements and rates

The Student's t-test indicated significant differences between the sexes and morphological characters. Summarized statistics and *p* values from the raw data, ratios and PERCRA index values are given in Table 8. According to the Student's t-test, we determined statistical significance difference of ( $p \leq 0.05$ ) between males and females in terms of characters from raw data and by the PERCRA index values (Parotoid length and Parotoid width).

Analysis of variance (ANOVA) has been performed using the raw data of all populations of mature individuals (Table 9). Significant differences ( $p \leq 0.05$ ) were found and discriminant analysis graphics were provided. (Table 10, Figures 25-27) According to ANOVA results, TBL, TL, NED, HL, PL, FLL, and DFHL characters were stated as different in males. NED and HW characters were stated as different in females.

Table 8. Body measurements, PERCRA index values and Student's t-test results of Gazipaşa population. 1: Raw data; 2: PERCRA; N: number of specimens; SD: Standard deviation; SE: Standard error of mean;  $p \leq 0.05$ . The other abbreviations of characters are given in Materials and Methods.

As a result of discriminant analysis of males, the distinction was done in two steps according to TL and NED/HL. In females, the distinction was also done in two steps according to NED and TL/TBL. When we look at the distinctions among all populations, we can see that the distinction was performed in four steps according to the TBL, NED/HL, ED and PW/PL characters.

Table 9. Results of One-way analysis of variance of all populations (ANOVA) (df: degrees of freedom, F: table values, P: significance level).

### *Lyciasalamandra atifi godmanni n. ssp.*

Holotype and type locality: ZMADYU 2013/18-6, male, collected by Bayram GÖÇMEN, M. ANIL & Onur OĞUZ on April 15, 2013 in Selge, Antalya, Turkey, 482 m. a.s.l.

Paratypes: ZMADYU 2012/19: 1-8, 2 males, 1 female, 5 juveniles collected by B. GÖÇMEN, B. AKMAN on March 2, 2012; 2013/18: 1-5, 7-18, 9 males, 11 females, 4 juveniles collected by B. GÖÇMEN, M. A. & O. OĞUZ on April 15, 2013 in Selge, Antalya, Turkey, 482 m. a.s.l.

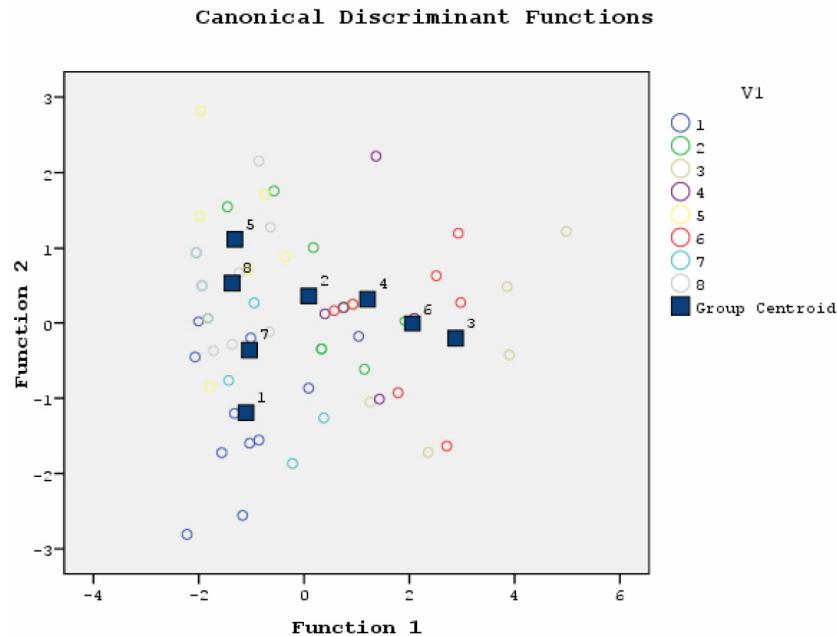

Figure 25. Discriminant (Distinction) distribution of males of all populations in the analysis. (1: Selge, 2: Fersin, 3: Dikmen, 4: Guzelbag, 5: Gündoğmuş, 6: Cebireis, 7: Türbelinaz, 8: Gazipaşa).

**Diagnosis:** Individuals of the Selge population have reddish dark brown ground colouration. The white stripes begin under the eye line on lateral sides and last until the fore limbs uninterruptedly. So, the individuals of the Selge are different from the other populations because of these morphological features. The population's serological results are different from the others as well (Figure 3).

**Etymology:** This subspecies is dedicated to Mr. Olaf GODMANN, who significantly contributed to *Lyciasalamandra* studies in Turkey.

**Description of the holotype:** Total body length 148 mm [100.89 Percra], tail length 71 mm [108.54 Percra]. Eyes big, eye diameter 6.43 mm [4.38 Percra]. Head length and head width 15.92 and 17.75 mm, respectively [20.70 and 12.10 Percra]. Parotoids distinct, parotoid length 12.42 mm [8.46 Percra] and parotoid width 8.85 mm [6.03 Percra]. Hind limb longer

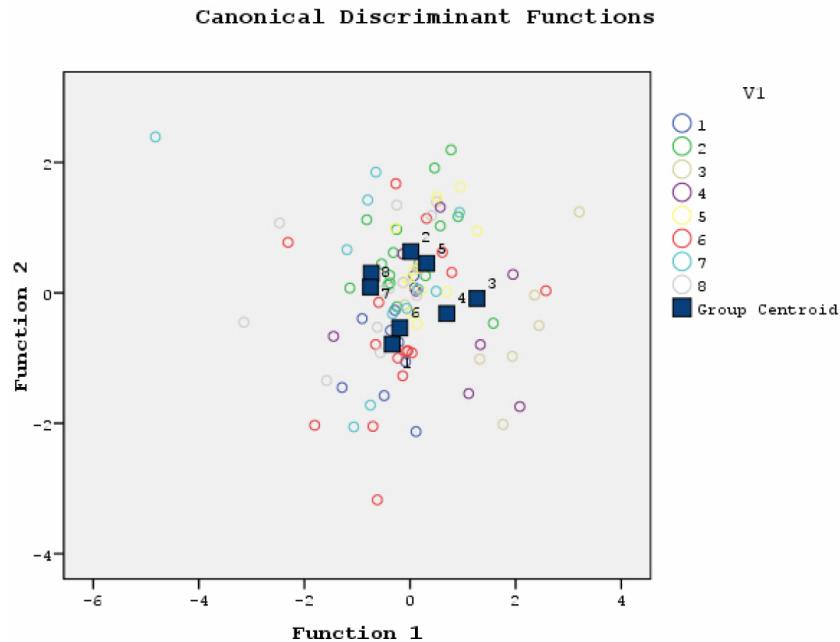

Figure 26. Discriminant (Distinction) distribution of females of all populations in the analysis. (1: Selge, 2: Fersin, 3: Dikmen, 4: Guzelbag, 5: Gündoğmuş, 6: Cebireis, 7: Türbelinaz, 8: Gazipaşa).

than fore limb, hind limb length 23.77 [16.20 Percra], fore limb length 24.2mm [16.49 Percra]. Nostril to eye distance 3.28 mm [2.23 Percra], distance between nostrils 5.43 mm [3.70 Percra]. Ratios HW/HL, TL/TBL, PW/PL and NED/HL are 1.11, 0.70, 0.71 and 0.21, respectively.

**Paratypes and variations:** Thirty one more specimens collected from Selge were designated as paratypes. Three of eleven males do not have any white spot on the dorsum. In females, two of ten specimens have reddish colouration in both dorsal and ventral sides of the tail and we did not came across the variations among juveniles. All the specimens has the same white stripe patterns on lateral sides.

**Habitat and ecology:** Specimens in the Selge population were found on a steep slope with high vegetation (Figure 1). The weather was humid and cloudy, it was noon and temperature was 19.7 °C. They inhabit the edge of a

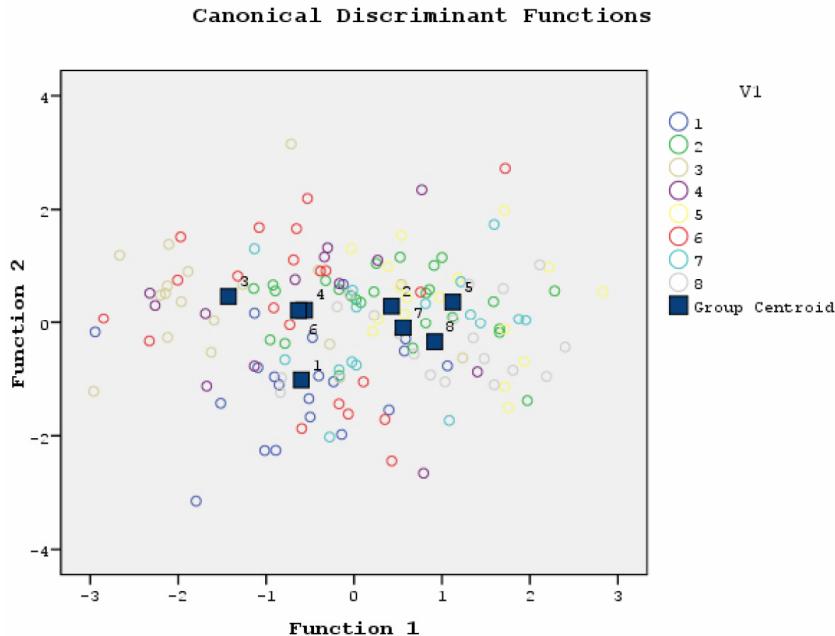

Figure 27. Discriminant (Distinction) distribution of mature specimens of all populations in the analysis. (1: Selge, 2: Fersin 3: Dikmen, 4: Guzelbag, 5: Gündoğmuş, 6: Cebireis, 7: Türbelinaz, 8: Gazipaşa).

steep slope at an elevation of 482 a.s.l.

#### *Lyciasalamandra atifi veithi* n. ssp.

Holotype and type locality: ZMADYU 2013/20-1, male, collected by Bayram GÖÇMEN, M. ANIL & Onur OĞUZ on March 16, 2013 in Dikmen village, Akseki, Antalya, Turkey, 889 m a.s.l.

Paratypes: ZMADYU 2012/17: 1-8, 4 females, 4 juveniles collected by B. GÖÇMEN, B. AKMAN, N. İĞCİ, M. VEITH, O. GODMANN on March 8, 2012; 2012/45: 1-2, 1 male, 1 female collected by B. GÖÇMEN, B. AKMAN on April 11, 2012; 2013/20: 2-15, 4 males, 6 female, 4 juveniles collected by B. GÖÇMEN, M. A. & O. OĞUZ on March 16, 2013 in Dikmen village, Akseki, Antalya, Turkey, 889 m. a.s.l.

Diagnosis: In Dikmen population, dark brown ground colour and reddish

fleshy coloured ventral part combine on lateral sides of the body uninterrupted and there are numerous small white spots and no uninterrupted white stripes on lateral sides. With the longest mean total length and absence of the white stripes on lateral sides, this population is different from the others.

**Etymology:** The subspecific epithet *veithi* is derived from Prof. Dr. Michael VEITH who made valuable contributions to the studies on *Lyciasalamandra* species in Turkey.

**Description of the holotype:** Total body length 153 mm [188.88 Percra], tail length 72 mm [92.21 Percra]. Eyes big, eye diameter 5.30 mm [6.54 Percra]. Head flat, head length and head width 17.32 and 12.68 mm, respectively [21.38 and 15.65 Percra]. Parotoids distinct, parotoid length 9.62 mm [11.87 Percra] and parotoid width 2.88 mm [3.55 Percra]. Hind limb longer than fore limb, hind limb length 26.78 [33.06 Percra], fore limb length 23.17 mm [28.60 Percra]. Nostril to eye distance 3.31 mm [4.08 Percra], distance between nostrils 4.48 mm [5.53 Percra]. Ratios HW/HL, TL/TBL, PW/PL and NED/HL are 0.73, 0.47, 0.29 and 0.19, respectively.

**Paratypes and variations:** Twenty four more species collected from Dikmen were designated as paratypes. One of the five males has light brown tail colouration regarding the other males and three of eleven females has light brown tail colouration regarding the other ones. In juveniles, yellow spots on the posterior of the parotoids are visible and in the dorsal side, there are numerous white spots on the head and dorsum. We could not encounter any variation among the juveniles.

**Habitat and ecology:** Specimens were found sheltering inside walls left over from ancient settlements. It was hard to reach them because of the continuing walls to underground. So, we could reach some of them by digging the mud which exist next to walls. The weather was humid and cloudy at a temperature of 17°C. The vegetation was thin and there were not much trees around (Figure 7). We observed that they shelter almost underground and they were very fearful against humans regarding to other populations.

#### ***Lyciasalamandra atifi kunti n. ssp.***

**Holotype and type locality:** ZMADYU 2012/46-7, female, collected by Bayram

GÖÇMEN, Bahadır AKMAN on April 12, 2012 in Güzelbağ, Turkey, 829 m. a.s.l.

**Paratypes:** ZMADYU 2012/46 1-6, 8-11, 6 females, 4 juveniles collected by B. GÖÇMEN, B. AKMAN on April 11, 2012; ZMADYU 2012/47: 1-9, 5 males, 3 females, 1 juvenile collected by B. GÖÇMEN, B. AKMAN on April 12, 2012; ZMADYU/2013-23: 1-8, 1 male, 3 females, 4 juveniles collected by B. GÖÇMEN, M. A. OĞUZ on March 16, 2013 in Güzelbağ, Antalya, Turkey, 829 m. a.s.l.

**Diagnosis:** There are markedly large and very intense white spots on the head and dorsum in both males and females. In the sides, there are fragmented and discontinuous white stripes which start under the eye level and go on between the fore and hind limbs. Sexes have also different pattern. Unlike males, white spots are smaller and less in number in females regarding the males. But nevertheless bigger than the other populations.

**Etymology:** This subspecies is dedicated to Kadir Boğaç KUNT who is an arachnologist in Turkey and contributed to science with valuable researches.

**Description of the holotype:** Total body length 110 mm [183.33 Percra], tail length 50 mm [83.33 Percra]. Eyes big, eye diameter 5.10 mm [8.50 Percra]. Head at, head length and head with 15.11 and 11.54 mm, respectively [25.18 and 19.23 Percra]. Parotoids distinct, parotoid length 7.36mm [12.26 Percra] and parotoid width 2.56 mm [4.26 Percra]. Hind limb longer than fore limb, hind limb length 23.008 [38.46 Percra], fore limb length 20.01mm [33.50 Percra]. Nostril to eye distance 2.87 mm [4.78 Percra], distance between nostrils 4.01 mm [6.68 Percra]. Ratios HW/HL, TL/TBL, PW/PL and NED/HL are 0.76, 0.45, 0.34 and 0.19, respectively.

**Paratypes and variations:** Twenty seven more specimens collected from the Güzelbağ were designated as paratypes. There are intense and markedly large white spots on the head and dorsum on both males and females. This situation similar with juveniles but two of ten juveniles have yellow flecks on the dorsal side of the tail instead of the dark brown colouration.

**Habitat and ecology:** The specimens in Güzelbağ population were found under white-striped limestone rocks and smooth open area. The weather was rainy, temperature of 18°C and elevation was 829 m. a.s.l. The vegeta-

tion is low and there are not trees around the field (Figure 13). White stripes on the rocks look like similar with the specimens' intense white spots.

## DISCUSSION

Among the eight isolated populations, this study describes three new subspecies of *Lyciasalamandra atifi* from Selge, Dikmen and Güzelbağ region in Antalya regarding morphology and serology.

Yıldız & Akman (2015) reported that the mean body length value of the subspecies *bayrami* is 136 mm (range: 102-171 mm) and Tok et al. (2016) also reported the mean body length of subspecies *oezi* is 139 mm (range: 127-154). These two values are close to each other and lower than the previous studies [158 mm (range: 134-176 mm) by Başoğlu (1967); 161 mm (range: 134-181 mm) by Baran & Üçüncü (1994); 141 mm (range: 105-164 mm) by Öz et al. (2004)]. We stated the mean body length value of the new subspecies *godmanni* n. ssp. is 142 mm (125-159). This value is higher than the subspecies *bayrami* and *oezi* as well. The mean body length value of the new subspecies *veithi* n. ssp. in Dikmen village is different from the other total body length values. It was calculated as 160 mm (range: 130-195 mm). Başoğlu & Baran (1977) calculated the largest specimen as 181 mm. According to these results, with 195 mm total body length, we have encountered the biggest adult specimens so far (Table 3). The third new subspecies *kunti* n. ssp. in Güzelbağ was calculated as 146 mm (range: 127-165) and this value is bigger than the subspecies both *bayrami* and *oezi* as well (Table 5). Thus, Dikmen population has the biggest mean of total body length value among all *L. atifi* populations.

*Lyciasalamandra atifi* has the largest range among other *Lyciasalamandra* species. The distribution of species was extended 75 km through eastern part of Gazipaşa and reported 1400 m above sea level in Cebireis mountain (Akman et al. 2011; Göçmen et al. 2013). According to Gebhard et al. (1990), *L. atifi* is exist around Manavgat stream. We made two different excursions to that location in November 2013, but we couldn't success to find any specimens.

Göçmen et al. (2013) mentioned that the individuals of Gazipaşa populations show some morphometric differences. They say that the specimens from around Gazipaşa, including juveniles, do not have yellow colouration and further research is required in order to clarify their taxonomic status. Although this study finished in 2015 as a Master Thesis by mentioning morphology, serology and statistics differences of Gazipaşa population and it was about to be published, this population was described as *Lyciasalamandra atifi oezi* by Tok et al. (2016) regarding to colour pattern. During our excursion, we noted that the specimens from Gazipaşa region where hiding under limestone slabs near the roots of *Arbutus arachnne* (Greek strawberry tree) plants, which retain water abundantly as well.

The Dikmen population was reported for the first time by Başoğlu & Baran (1977). According to their investigation, this population was similar in morphology with the type locality. But we found that the Dikmen population is not compatible with the type locality because of the absence of lateral stripes on the sides. Individuals in the Dikmen population are also extremely fearful of humans when compared with the individuals of other populations. Furthermore, Fersin, Gündoğmuş and Türbelinaz populations fit properly to the diagnostic features of the description of *Lyciasalamandra atifi* (Başoğlu 1967). Among all populations, reddish dark brown colouration is visible in Selge population regarding the others' colour pattern and the white stripes on lateral sides are only visible uninterruptedly in the Selge population. So, we named the Selge population as *Lyciasalamandra atifi godmanni* n. ssp.

We stated the Dikmen population as *Lyciasalamandra atifi veithi* n. ssp. especially because of the absence of the white stripes on lateral sides, being isolated from the others, having serological differences and mentioned morphometric features on this study. Güzelbağ population was also recorded for the first time by Göçmen et al. (2013) and they say that Güzelbağ populations show some morphometric differences by being much more white-spotted than any other known *L. atifi* populations. There are big, with very intensive white spots on the surfaces of individuals. Our study results agree with them and we named the Güzelbağ population as *Lyciasalamandra atifi kunti* n. ssp.

As we can see the results of ANOVA and discriminant analysis, almost all the populations were calculated as different according to statistics (Table

10, 11, 12). But we applied serology techniques to be sure the distinction degrees among the populations as well. Electropherograms and densitometric curves of blood samples were taken from two males and two females per population and compared with each other. Equal amounts of albumin and pre-albumin proteins were defined as one fraction in all the populations. It was observed that the males in Selge, Fersin, Gündoğmuş, Türbelinaz and *Lyciasalamandra atifi bayrami* populations' globulin areas were divided into 10 fractions. However, the males of the new subspecies *veithi* n. ssp. from Dikmen and *kunti* n. ssp. from Güzelbağ populations were divided into 9 fractions at the globulin areas. Globulin areas in females of the Fersin, the new subspecies *veithi* and *kunti* n. ssp. and Türbelinaz populations were divided into 9 fractions. Globulin areas in females of the new subspecies *godmanni* n. ssp. from Selge and *L. atifi bayrami* populations were divided into 10. In the females of Gündoğmuş and *L. atifi oezi* populations' globulin areas were divided into 11 fractions. Furthermore, unlike other populations, the greatest fraction number in globulin areas was observed in the *Lyciasalamandra atifi oezi* population for the first time. Males and females both had 11 fractions at globulin areas.

Veith et al. (2008) also showed that the Selge population has different haplotypes among the *Lyciasalamandra atifi* populations. It was determined that except of the Fersin, Gündoğmuş and Türbelinaz populations, the other *Lyciasalamandra atifi* populations which are isolated in different habitats, are not compatible with the diagnostic characteristics of the species description given by Başoğlu (1967). The distribution of these isolated populations is in an area about 190 km from Selge to Gazipaşa. Accordingly, it was determined that the some isolated populations in the distribution area are different from each other in morphological, colour-pattern and serological aspects. Examination of the blood-serum protein analysis shows that they are different, and populations with equal numbers of blood serum proteins appear to be incompatible among each other in terms of colour-pattern characteristics. There are also differences among them in terms of measurements and ratios in statistics. Thus, the taxonomic status of each population was reassessed and revealed that three new subspecies (*L. atifi godmanni* n. ssp., *L. atifi veithi* n. ssp. and *L. atifi kunti* n.

ssp.) had to be established. However, the taxonomic status of populations will become more clear with the conclusion of ongoing genetic studies.

**ACKNOWLEDGEMENT.** *The study was produced from MSc thesis of first author and supervised by second author. We would like to express our appreciation to the Ege University Scientific Research Project Commission, which supported this study in a Project (No: 2013-Fen-010) and also grateful to Dr. Bahadır AKMAN and PhD student Mert KARIŞ (Ege University, Faculty of Science, Department of Biology, Zoology Section) for their assistances during our trips.*
